## Speaking Serial R with a Parallel Accent

The content of this presentation is based in part on the **pbdDEMO** vignette *Speaking Serial R with a Parallel Accent* 

http://goo.gl/HZkRt

It contains more examples, and sometimes added detail.

# About This Presentation

pbdMPI

#### Installation Instructions

Installation instructions for setting up a pbdR environment are available:

This includes instructions for installing R, MPI, and pbdR.

# Contents

- Introduction to pbdMPI
- The Generalized Block Distribution
- Basic Statistics Examples
- Introduction to pbdDMAT and the DMAT Structure
- Examples Using pbdDMAT
- Wrapup

# Contents

pbdMPI

- Introduction to pbdMPI
  - Managing a Communicator
  - Reduce, Gather, Broadcast, and Barrier
  - Other pbdMPI Tools

# Message Passing Interface (MPI)

- MPI: Standard for managing communications (data and instructions) between different nodes/computers.
- Implementations: OpenMPI, MPICH2, Cray MPT, . . .
- Enables parallelism (via communication) on distributed machines.
- Communicator: manages communications between processors.

## MPI Operations (1 of 2)

 Managing a Communicator: Create and destroy communicators.

init() — initialize communicator
finalize() — shut down communicator(s)

 Rank query: determine the processor's position in the communicator.

comm.rank() — "who am I?"
comm.size() — "how many of us are there?"

• **Printing**: Printing output from various ranks.

comm.print(x)
comm.cat(x)

**WARNING**: only use these functions on *results*, never on yet-to-be-computed things.

2/70

# Quick Example 1

### Rank Query: 1\_rank.r

```
library(pbdMPI, quiet = TRUE)
  init()
3
  my.rank <- comm.rank()</pre>
  comm.print(my.rank, all.rank=TRUE)
6
  finalize()
```

### Execute this script via:

mpirun -np 2 Rscript 1\_rank.r

#### Sample Output:

```
COMM \cdot RANK = O
  [1] 0
2
  COMM.RANK = 1
  [1] 1
```

pbdMPI

0000

# Quick Example 2

#### Hello World: 2\_hello.r

```
library(pbdMPI, quiet=TRUE)
init()

comm.print("Hello, world")

comm.print("Hello again", all.rank=TRUE, quiet=TRUE)

finalize()
```

#### Execute this script via:

```
mpirun -np 2 Rscript 2_hello.r
```

Stats eg's

#### Sample Output:

```
COMM.RANK = 0
[1] "Hello, world"
[1] "Hello again"
[1] "Hello again"
```

Reduce, Gather, Broadcast, and Barrier

## **MPI** Operations

- Reduce

### MPI Operations (2 of 2)

- Reduction: each processor has a number x; add all of them up, find the largest/smallest, . . . . reduce(x, op='sum') — reduce to one allreduce(x, op='sum') — reduce to all
- Gather: each processor has a number; create a new object on some processor containing all of those numbers. gather(x) — gather to one allgather(x) — gather to all
- Broadcast: one processor has a number x that every other processor should also have. bcast(x)
- Barrier: "computation wall"; no processor can proceed until all processors can proceed. barrier()

## MPI Package Controls

The .SPMD.CT object allows for setting different package options with **pbdMPI**. See the entry *SPMD Control* of the **pbdMPI** manual for information about the .SPMD.CT object:

http://cran.r-project.org/web/packages/pbdMPI/pbdMPI.pdf

Stats eg's

pbdMPI

00000

#### Random Seeds

**pbdMPI** offers a simple interface for managing random seeds:

- comm.set.seed(diff=TRUE) Independent streams via the rlecuyer package.
- comm.set.seed(seed=1234, diff=FALSE) All processors use the same seed seed=1234
- comm.set.seed(diff=FALSE) All processors use the same seed, determined by processor 0 (using the system clock and PID of processor 0).

pbdDMAT eg's

### Other Helper Tools

**pbdMPI** Also contains useful tools for Manager/Worker and task parallelism codes:

- Task Subsetting: Distributing a list of jobs/tasks get.jid(n)
- \*ply: Functions in the \*ply family. pbdApply(X, MARGIN, FUN, ...) — analogue of apply() pbdLapply(X, FUN, ...) — analogue of lapply() pbdSapply(X, FUN, ...) — analogue of sapply()

Other pbdMPI Tools

Start by loading the package:

```
1 library(pbdMPI, quiet = TRUE)
```

Stats eg's

② Always initialize before starting and finalize when finished:

```
init()

# ...

finalize()
```

# Distributing Data

**Problem:** How to distribute the data

$$x = \begin{bmatrix} x_{1,1} & x_{1,2} & x_{1,3} \\ x_{2,1} & x_{2,2} & x_{2,3} \\ x_{3,1} & x_{3,2} & x_{3,3} \\ x_{4,1} & x_{4,2} & x_{4,3} \\ x_{5,1} & x_{5,2} & x_{5,3} \\ x_{6,1} & x_{6,2} & x_{6,3} \\ x_{7,1} & x_{7,2} & x_{7,3} \\ x_{8,1} & x_{8,2} & x_{8,3} \\ x_{9,1} & x_{9,2} & x_{9,3} \\ x_{10,1} & x_{10,2} & x_{10,3} \end{bmatrix}_{10 \times}$$

#### The GBD Data Structure

**GBD** 

0000

Throughout the examples, we will make use of the Generalized Block Distribution, or GBD distributed matrix structure.

- GBD is distributed. No processor owns all the data.
- ② GBD is non-overlapping. Rows uniquely assigned to processors.

Stats eg's

- 3 GBD is row-contiguous. If a processor owns one element of a row, it owns the entire row.
- 4 GBD is globally row-major, locally column-major.
- GBD is often locally balanced, where each processor owns (almost) the same amount of data. But this is not required.

_		
$x_{1,1}$	$x_{1,2}$	<i>X</i> 1,3
$x_{2,1}$	$x_{2,2}$	$x_{2,3}$
x <sub>3,1</sub>	X3,2	X3,3
X4,1	X4,2	X4,3
<i>X</i> 5,1	X5,2	<i>X</i> 5,3
<i>x</i> <sub>6,1</sub>	<i>X</i> <sub>6,2</sub>	<i>x</i> <sub>6,3</sub>
x <sub>7,1</sub>	X7,2	<i>X</i> 7,3
X8,1	X8,2	X8,3
X9,1	X9,2	<i>X</i> 9,3
X <sub>10,1</sub>	X <sub>10,2</sub>	X <sub>10,3</sub>

- The last row of the local storage of a processor is adjacent (by global row) to the first row of the local storage of next processor (by communicator number) that owns data.
- GBD is (relatively) easy to understand, but can lead to bottlenecks if you have many more columns than rows.

GBD: Example 2

### Quick Comment for GBD

000

Local pieces of GBD distributed objects will be given the suffix .gbd to visually help distinguish them from global objects. This suffix carries no semantic meaning.

## Contents

  - pbdMPI Example: Linear Regression

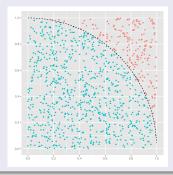

pbdMPI Example: Monte Carlo Simulation

### Example 1: Monte Carlo Simulation

Sample N uniform observations  $(x_i, y_i)$  in the unit square  $[0,1] \times [0,1]$ . Then

$$\pi pprox 4\left(rac{\#\ \textit{Inside Circle}}{\#\ \textit{Total}}
ight) = 4\left(rac{\#\ \textit{Blue}}{\#\ \textit{Blue} + \#\ \textit{Red}}
ight)$$

pbdMPI

## Example 1: Monte Carlo Simulation GBD Algorithm

- Let *n* be big-ish; we'll take n = 50,000.
- Generate an  $n \times 2$  matrix x of standard uniform observations.
- **3** Count the number of rows satisfying  $x^2 + y^2 < 1$
- Ask everyone else what their answer is; sum it all up.
- 5 Take this new answer, multiply by 4 and divide by n
- o If my rank is 0, print the result.

pbdMPI Example: Monte Carlo Simulation

#### Example 1: Monte Carlo Simulation Code

#### Serial Code

```
N <- 50000
X <- matrix(runif(N * 2), ncol=2)</pre>
r \leftarrow sum(rowSums(X^2) \leftarrow 1)
PI <- 4*r/N
print(PI)
```

#### Parallel Code

```
library(pbdMPI, quiet = TRUE)
  init()
  comm.set.seed(diff=TRUE)
  N.gbd <- 50000 / comm.size()
  X.gbd <- matrix(runif(N.gbd * 2), ncol = 2)</pre>
  r.gbd <- sum(rowSums(X.gbd^2) <= 1)
  r <- allreduce(r.gbd)
  PI <- 4*r/(N.gbd * comm.size())
  comm.print(PI)
11
  finalize()
```

pbdMPI Example: Monte Carlo Simulation

### Note

For the remainder, we will exclude loading, init, and finalize calls.

pbdMPI Example: Sample Covariance

### Example 2: Sample Covariance

$$cov(x_{n \times p}) = \frac{1}{n-1} \sum_{i=1}^{n} (x_i - \mu_x) (x_i - \mu_x)^T$$

pbdMPI

# Example 2: Sample Covariance GBD Algorithm

- lacktriangle Determine the total number of rows N.
- 2 Compute the vector of column means of the full matrix.
- 3 Subtract each column's mean from that column's entries in each local matrix.
- Ompute the crossproduct locally and reduce.
- **5** Divide by N-1.

### Example 2: Sample Covariance Code

### Serial Code

```
1  N <- nrow(X)
2  mu <- colSums(X) / N
3
4  X <- sweep(X, STATS=mu, MARGIN=2)
5  Cov.X <- crossprod(X) / (N-1)
6
7  print(Cov.X)</pre>
```

### Parallel Code

```
1 N <- allreduce(nrow(X.gbd), op="sum")
2 mu <- allreduce(colSums(X.gbd) / N, op="sum")
3 
4 X.gbd <- sweep(X.gbd, STATS=mu, MARGIN=2)
5 Cov.X <- allreduce(crossprod(X.gbd), op="sum") / (N-1)
6 
7 comm.print(Cov.X)</pre>
```

pbdMPI Example: Linear Regression

### Example 3: Linear Regression

Find  $\beta$  such that

$$\mathsf{y} = \mathsf{X} oldsymbol{eta} + oldsymbol{\epsilon}$$

When **X** is full rank,

$$\hat{\boldsymbol{\beta}} = (\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \mathbf{y}$$

pbdMPI

# Example 3: Linear Regression GBD Algorithm

- Locally, compute  $tx = x^T$
- ② Locally, compute A = tx \* x. Query every other processor for this result and sum up all the results.
- **1** Locally, compute B = tx \* y. Query every other processor for this result and sum up all the results.
- Locally, compute  $A^{-1} * B$

# Example 3: Linear Regression Code

### Serial Code

```
1 tX <- t(X)
2 A <- tX %*% X
3 B <- tX %*% y
4 ols <- solve(A) %*% B
```

### Parallel Code

```
tX.gbd <- t(X.gbd)
tX.gbd <- t(X.gbd)
tX.gbd <- t(X.gbd %*% X.gbd, op = "sum")
B <- allreduce(tX.gbd %*% y.gbd, op = "sum")
tols <- solve(A) %*% B</pre>
```

pbdMPI Example: Linear Regression

# Advanced MPI Exercises I

- Write a script that will have each processor randomly take a sample of size 1 of TRUE and FALSE. Have each processor print its result.
- Modify the script in Exercise 1 above to determine if any processors sampled TRUE. Do the same to determine if all processors sampled TRUE. In each case, print the result. Compare to the functions comm.all() and comm.any().
- Generate 50,000,000 (total) random normal values in parallel on 2, 4, and 8 processors. Time each run.

# Advanced MPI Exercises II

- Oistribute the matrix x <- matrix(1:24, nrow=12) in GBD format across 4 processors and call it x.spmd.
  - Add x.spmd to itself.
  - 2 Compute the mean of x.spmd.
  - 3 Compute the column means of x.spmd.

Introduction to Distributed Matrices

### Distributed Matrices

Most problems in data science are matrix algebra problems, so:

Distributed matrices ⇒ Handle Bigger data

pbdMPI

### Distributed Matrices

High level OOP allows *native* serial R syntax:

```
1 x <- x[-1, 2:5]

2 x <- log(abs(x) + 1)

3 xtx <- t(x) %*% x

4 ans <- svd(solve(xtx))
```

However. . .

Stats eg's

Introduction to Distributed Matrices

### Distributed Matrices

### DMAT:

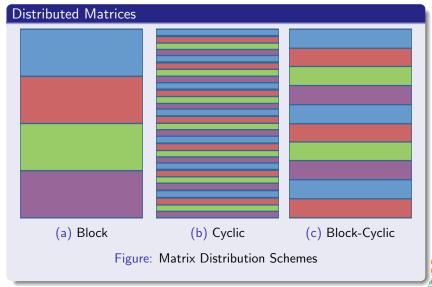

- Distributed MATrix data structure.
- No single processor should hold all of the data.
- Block-cyclic matrix distributed across a 2-dimensional grid of processors.
- Very robust, but confusing data structure.

Introduction to Distributed Matrices

### Distributed Matrices

The data structure is a special R class (in the OOP sense) called ddmatrix. It is the "under the rug" storage for a block-cyclic matrix distributed onto a 2-dimensional processor grid.

### with prototype

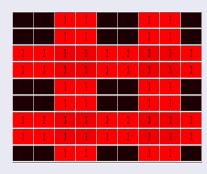

```
\label{eq:new("ddmatrix")} \text{new("ddmatrix")} = \begin{cases} \textbf{Data} &= \texttt{matrix}(0.0) \\ \textbf{dim} &= \texttt{c}(1,1) \\ \textbf{Idim} &= \texttt{c}(1,1) \\ \textbf{bldim} &= \texttt{c}(1,1) \\ \textbf{CTXT} &= 0.0 \end{cases}
```

IPMbda

### Distributed Matrices: The Data Structure

Example: an  $9 \times 9$  matrix is distributed with a "block-cycling" factor of  $2 \times 2$  on a  $2 \times 2$  processor grid:

$$= \begin{cases} \textbf{Data} &= \texttt{matrix}(\dots) \\ \textbf{dim} &= \texttt{c}(9, 9) \\ \textbf{Idim} &= \texttt{c}(\dots) \\ \textbf{bIdim} &= \texttt{c}(2, 2) \\ \textbf{CTXT} &= 0 \end{cases}$$

See http://acts.nersc.gov/scalapack/hands-on/datadist.html

### The DMAT Data Structure

- ① DMAT is distributed. No one processor owns all of the matrix.
- 2 DMAT is non-overlapping. Any piece owned by one processor is owned by no other processors.
- ① DMAT can be row-contiguous or not, depending on the processor grid and blocking factor used.
- OMAT is locally column-major and globally, it depends...
- GBD is a generalization of the one-dimensional block DMAT distribution. Otherwise there is no relation.
- O DMAT is confusing, but very robust.

### Pros and Cons of This Data Structure

### Pros

 Fast for distributed matrix computations

### Cons

Literally everything else

This is why we hide most of the distributed details.

The details are there if you want them (you don't want them).

### Distributed Matrix Methods

**pbdDMAT** has over 100 methods with *identical* syntax to R:

- `[`, rbind(), cbind(), ...
- lm.fit(), prcomp(), cov(), ...
- `%\*%`, solve(), svd(), norm(), ...
- median(), mean(), rowSums(), ...

### Serial Code

1 cov(x)

### Parallel Code

1 cov(x)

pbdMPI

# Comparing pbdMPI and pbdDMAT

### pbdMPI:

- MPI + sugar.
- GBD not the only structure pbdMPI can handle (just a useful convention).

### pbdDMAT:

- More of a software package.
- DMAT structure must be used for pbdDMAT.
- If the data is not 2d block-cyclic compatible, DMAT will definitely give the wrong answer.

pbdMPI

### Quick Comments for Using pbdDMAT

Start by loading the package:

```
1 library(pbdDMAT, quiet = TRUE)
```

② Always initialize before starting and finalize when finished:

```
1 init.grid()
2
3 # ...
4
5 finalize()
```

Oistributed DMAT objects will be given the suffix .dmat to visually help distinguish them from global objects. This suffix carries no semantic meaning.

pbdMPI

# Advanced DMAT Exercises I

- Subsetting, selection, and filtering are basic matrix operations featured in R. The following may look silly, but it is useful for data processing. Let x.dmat <- ddmatrix(1:30, 10, 3). Do the following:
  - y.dmat <- x.dmat[c(1, 5, 4, 3), ] y.dmat  $\leftarrow$  x.dmat[c(10:3, 5, 5), ] y.dmat <- x.dmat[1:5, 3:1]</pre>
  - y.dmat <- x.dmat[x.dmat[, 2] > 13, ]  $v.dmat \leftarrow x.dmat[x.dmat[, 2] > x.dmat[, 3], ]$ v.dmat <- x.dmat[, x.dmat[2,] > x.dmat[3, ]] v.dmat <- x.dmat[c(1, 3, 5), x.dmat[, 2] >x.dmat[, 3]]

# Statistics Examples with pbdDMAT Advanced DMAT Exercises II

- The method crossprod() is an optimized form of the crossproduct computation t(x.dmat) %\*% x.dmat. For this exercise, let x.dmat <- ddmatrix(1:30, nrow=10, ncol=3).
  - Verify that these computations really do produce the same results.
  - 2 Time each operation. Which is faster?

Stats eg's

The prcomp() method returns rotations for all components. Computationally verify by example that these rotations are orthogonal, i.e., that their crossproduct is the identity matrix.
